Abstract—Memory persistency models enable maintaining recoverable data structures in persistent memories and prior work has proposed ISA-level persistency models. In addition to these models, we argue for extending language-level memory models to provide persistence semantics. We present a taxonomy of guarantees a language-level persistency model could provide and characterize their programmability and performance.

■ **PERSISTENT MEMORIES (PMs)**, such as Intel's upcoming 3D XPoint memory,¹ offer the durability of disk, better density than DRAM, and DRAM-like performance. These properties have spawned myriad efforts to adopt PM in computer systems. A particularly disruptive potential PM use case is to host in-memory recoverable data structures. PMs blur the traditional divide between a byte-addressable, volatile main memory, and a block-addressable, persistent storage. This memory

allows programmers to directly manipulate recoverable data structures using processor loads and stores, rather than relying on performance-sapping software intermediaries like the operating system and file system.²

Ensuring the recoverability of data structures requires programmers to be able to control the order stores reach PM. With out-of-order processing and write-back caching, stores may reach PM out of order, compromising data structure recoverability. Existing systems do not provide efficient mechanisms to enforce the order in which stores are written back. Recent work has proposed *persistency models* to provide programmers an interface to control the order persistent stores write

Cache: Importance

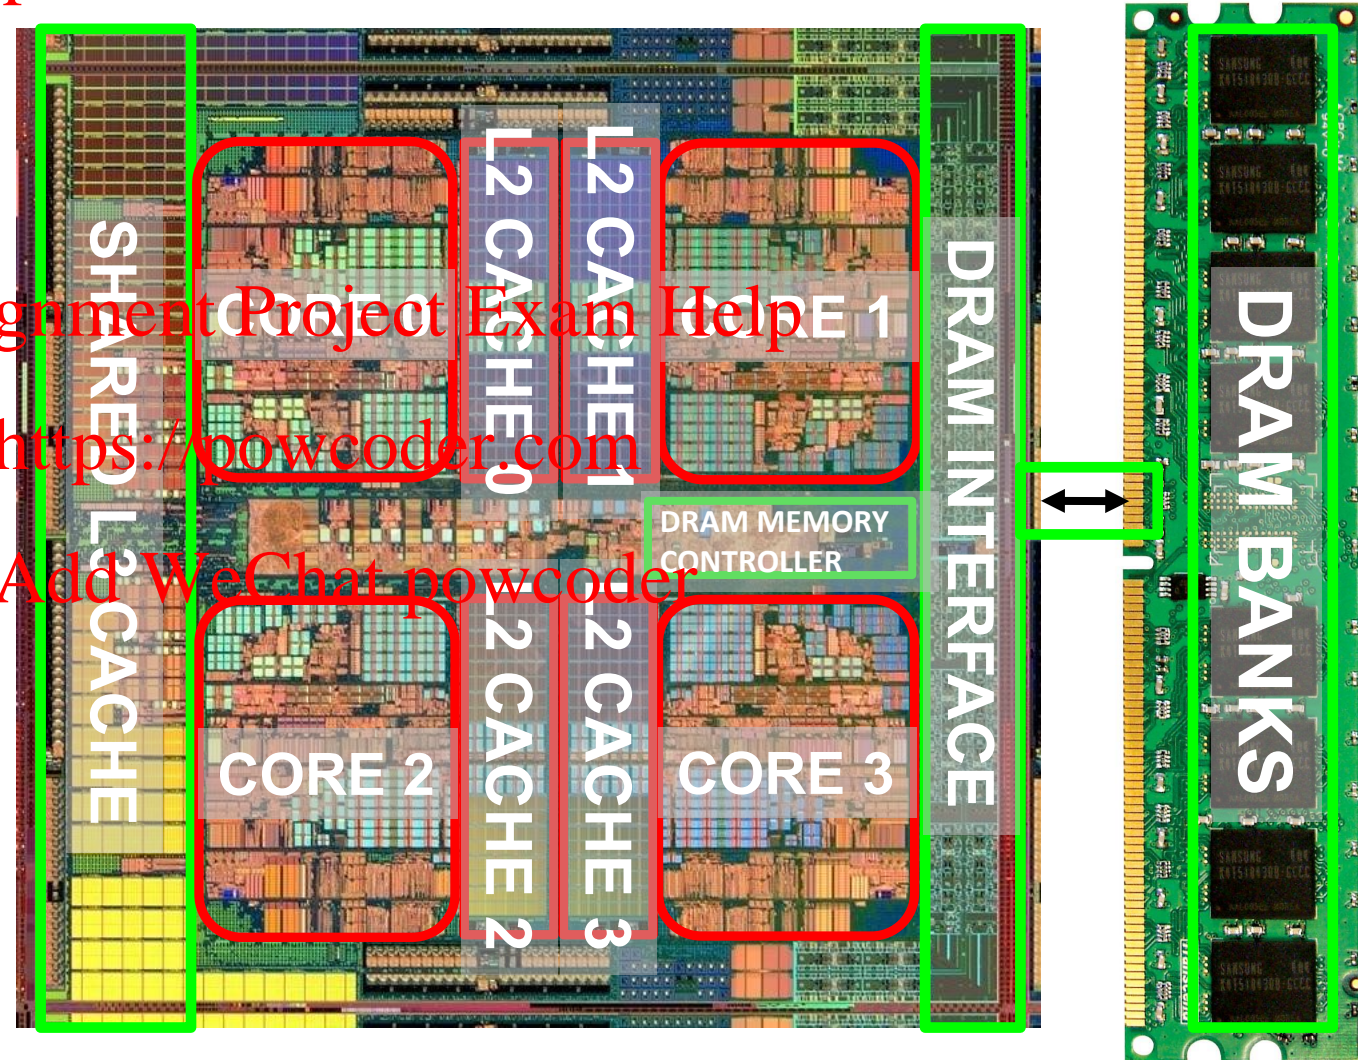

Add WeChat powcoder

Caches consume
most of a processor's die area

Assignment Project Exam Help

<https://www.powcoder.com>

Add WeChat powcoder

Assignment Project Exam Help

Review: A simple cache architecture

V/I	Tag Array	Data Array	
1	Addr-3	data-3	cache line
0	Addr-5	data-5	
0	Addr-6	data-6	cache block
1	Addr-7	data-7	

<https://powcoder.com>

A cache memory consists of multiple tag/block pairs (called **cache lines**)

Add WeChat powcoder

Address is searched across all tags in parallel.

At most one tag will match

If there is a tag match, it is a cache **HIT**

If there is no tag match, it is a cache **MISS**

Cache data that is likely to be used in future – exploit temporal locality

Assignment Project Exam Help

Temporal Locality

Add WeChat powcoder

The principle of **temporal locality** in program references says that if you access a memory location (e.g., 0x1000) you will be more likely to re-access that location (e.g., 0x1000) than you will be to reference some other random location

Assignment Project Exam Help

Temporal locality says any miss location should be placed into the cache

<https://powcoder.com>

It is the most recent reference location

Add WeChat powcoder

Temporal locality says that data in least recently referenced (or least recently used – **LRU**) cache line should be **evicted** to make room for the new line

Because the re-access probability falls over time as a cache line isn't referenced, the LRU line is least likely to be re-referenced

Assignment Project Exam Help

Tracking LRU

Add WeChat powcoder

Naïve method

Maintain LRU_rank per cache line

Set the LRU_rank of newly accessed block to 0. Increment others by 1.

Replace cache line with highest LRU_rank

Area overhead: $\log(\text{number of cache lines})$ per cache line

<https://powcoder.com>

LRU with least area overhead

permutations for N cache lines is $n!$

need just $\log(n!)$ bits for N cache lines

Assignment Project Exam Help

Problem — AMAT

Add WeChat powcoder

Assume main memory access time does not include cache access time.

Suppose that accessing a cache takes 10ns while accessing main memory in case of cache-miss takes 100ns. What is the average memory access time if the cache hit rate is 97%?

<https://powcoder.com>

Add WeChat powcoder

To improve performance, the cache size is increased. It is determined that this will increase the hit rate by 1%, but it will also increase the time for accessing the cache by 2ns. Will this improve the overall average memory access time?

Assignment Project Exam Help

Problem —AMAT

Add WeChat powcoder

Suppose that accessing a cache takes 10ns while accessing main memory in case of cache-miss takes 100ns. What is the average memory access time if the cache hit rate is 97%?

$$AMAT = 10 + (1 - 0.97) * 100 = 13 \text{ ns}$$

Assignment Project Exam Help

<https://powcoder.com>

To improve performance, the cache size is increased. It is determined that this will increase the hit rate by 1%, but it will also increase the time for accessing the cache by 2ns. Will this improve the overall average memory access time?

Add WeChat powcoder

$$AMAT = 12 + (1 - 0.98) * 100 = 14 \text{ ns}$$

Assignment Project Exam Help

<https://powcoder.com>

Cache bigger units than bytes

Add WeChat powcoder

Each block has a single tag, and blocks can be whatever size we choose.

Assignment Project Exam Help

Increasing cache block size reduces (tag and other) overhead

Case 1:

Block size: 1 byte

1	0	74
1	6	160

V tag data (block)

Bits per tag

$= \log_2(\text{number of blocks in memory})$

$= \log_2(16) = 4 \text{ bits}$

Case 2:

Block size: 2 bytes

1	0	74	110
1	6	160	170

V tag data (block)

Bits per tag

$= \log_2(\text{number of blocks in memory})$

$= \log_2(8) = 3 \text{ bits}$

Memory		Block Case1	Block Case2
0	74	0	0
1	110	1	0
2	120	2	1
3	130	3	1
4	140	4	2
5	150	5	2
6	160	6	3
7	170	7	3
8	180	8	4
9	190	9	4
10	200	10	5
11	210	11	5

Spatial Locality

Add WeChat powcoder

When we accessed address 1, we also brought in address 0.

This turned out to be a good thing since we later referenced address 0 and found it in the cache.

Assignment Project Exam Help

Spatial locality in a program says that if we reference a memory location (e.g., 1000), we are more likely to reference a location near it (e.g. 1001, 999) than some random location.

Importance of Cache on Performance:

Cache Aware code can be several times faster than non-Aware code

```
#include<stdio.h>
#include<stdlib.h>
```

```
#define N 20000
int arrayInt[N][N];
```

```
int main(int argc, char **argv)
{
    int i, j;
    int count = 0;

    for(i=0; i< N; i++)
        for(j = 0; j < N; j++ )
        {
            count++;
            arrayInt[i][j] = 10;
        }

    printf("Count :%d\n", count);
}
```

```
#include<stdio.h>
#include<stdlib.h>
```

```
#define N 20000
int arrayInt[N][N];
```

```
int main(int argc, char **argv)
{
    int i, j;
    int count = 0;

    for(i=0; i< N; i++)
        for(j = 0; j < N; j++ )
        {
            count++;
            arrayInt[j][i] = 10;
        }

    printf("Count :%d\n", count);
}
```

Assignment Project Exam Help

Basic Cache organization

Add WeChat powcoder

Decide on the block size

How? Simulate lots of different block sizes and see which one gives the best performance

Common cache block sizes: 32, 64, or 128 bytes

Larger block sizes reduce cache area overhead by:

Reducing number of cache lines (therefore, number of tags and other meta-data)

Reducing each tag size

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

Address

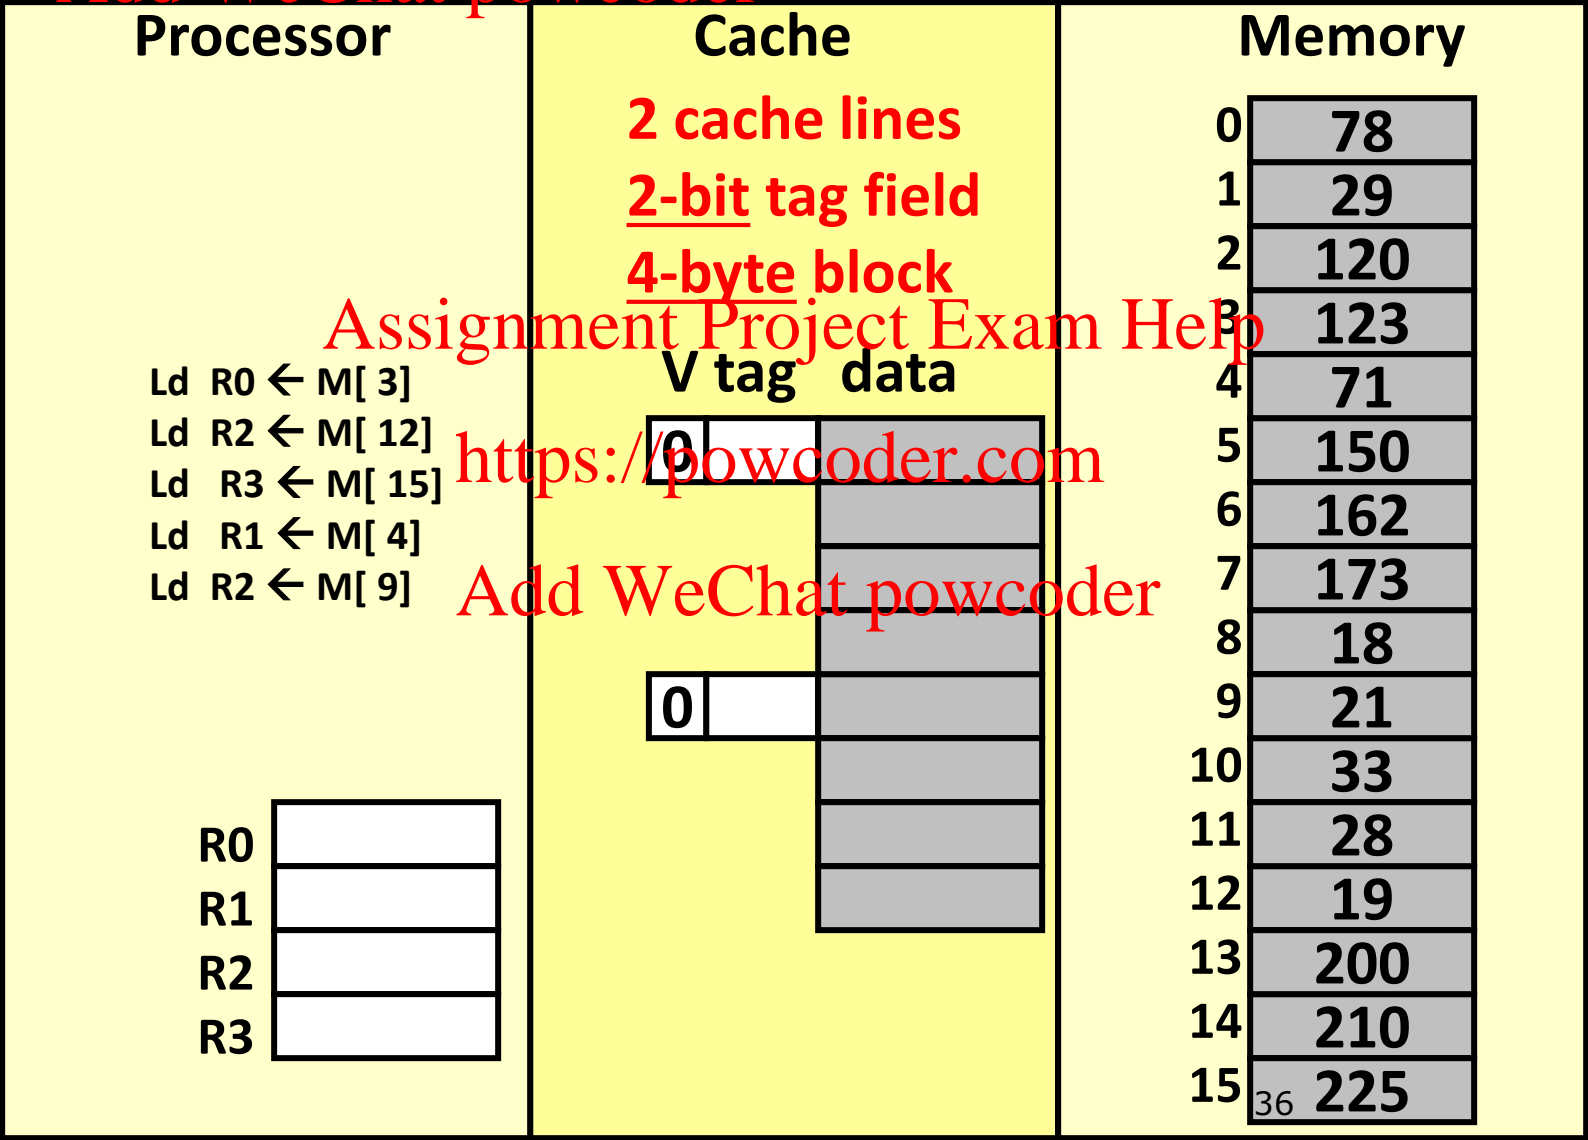

Block size = $2^{\text{block_offset}}$

$\text{sizeof}(\text{block_offset}) = \log_2(\text{block_size})$

Tag size = address_size - block_offset_size

Assignment Project Exam Help

Class Problem 1

Add WeChat powcoder

Given a cache with the following configuration: cache size is 8 bytes, block size is 2 bytes, *fully associative*, LRU replacement. The memory address size is 16 bits and is byte addressable.

1. How many bits are for each tag? How many blocks in the cache?

Assignment Project Exam Help

2. For the following reference stream, indicate whether each reference is a hit or miss: 0, 1, 3, 5, 12, 1, 2, 9, 4

<https://powcoder.com>

3. What is the hit rate?

Add WeChat powcoder

4. How many bits are needed for storage overhead for each block?

Assignment Project Exam Help

Class Problem 1

Add WeChat powcoder

Given a cache with the following configuration: cache size is 8 bytes, block size is 2 bytes, *fully associative*, LRU replacement. The memory address size is 16 bits and is byte addressable. Assume 2 bits per cache line to implement LRU.

1. How many bits are for each tag? How many blocks in the cache?

Tag = $16 - 1$ (block offset) = 15 bits,
2 byte blocks, 8 bytes total = 4 blocks.

<https://powcoder.com>

2. For the following reference stream, indicate whether each reference is a hit or miss: 0, 1, 3, 5, 12, 1, 2, 9, 4

M, H, M, M, M, H, H, M, M

3. What is the hit rate? $3/9 = 33\%$

4. How many bits are needed for storage overhead for each block?

Overhead = 15 (Tag) + 1 (V) + 2 (LRU) = 18 bits

We are assuming 2 bits per cache line to store the LRU rank.

More efficient solutions for LRU exists: $\log_2(\#cache_lines!) = \log_2(4!) = 5$ bits

Assignment Project Exam Help

Class Problem 2—Storage overhead

Consider the following cache:

32-bit byte addressable ISA

Cache size : 64KB (kilo-bytes) = $64 * 8$ kilo-bits = 512 Kilo-bits

Cache block size : 64 Bytes

Write-allocate, write-back, fully associative

Recall: 1 kilobyte = 1024 bytes (NOT 1000 bytes!)

What is the cache area overhead (tags, valid, dirty, LRU)?

Assignment Project Exam Help

Class Problem 2—Storage overhead

Consider the following cache:

32-bit byte addressable ISA

Cache size : 64KB (kilo-bytes) = $64 * 8$ kilo-bits = 512 Kilo-bits

Cache block size : 64 Bytes

Write-allocate, write-back, fully associative

Recall: 1 kilobyte = 1024 bytes (NOT 1000 bytes!)

What is the cache area overhead (tags, valid, dirty, LRU)? Assume $\log(\#blocks)$ bits for LRU.

Tag = 32 (Address) – 6 (block offset) = 26 bits

#blocks = $64K / 64$ = 1024

LRU bits = $\log(\#blocks)$ = 10 bits

Overhead per block = $26(\text{Tag}) + 1(V) + 1(D) + 10(\text{LRU})$ = 38 bits

Total overhead for cache = $38 \text{ bits} * \#blocks = 38 * 1024$ = 38912 bits

What about stores?

Add WeChat powcoder

Where should you write the result of a store to an address X?

If address X is in the cache

Write to the cache.

Should we also write to memory?

(yes - write-through policy)

(no - write-back policy – write only when modified cache block is evicted)

Add WeChat powcoder

If address X is not in the cache

Allocate address in the cache?

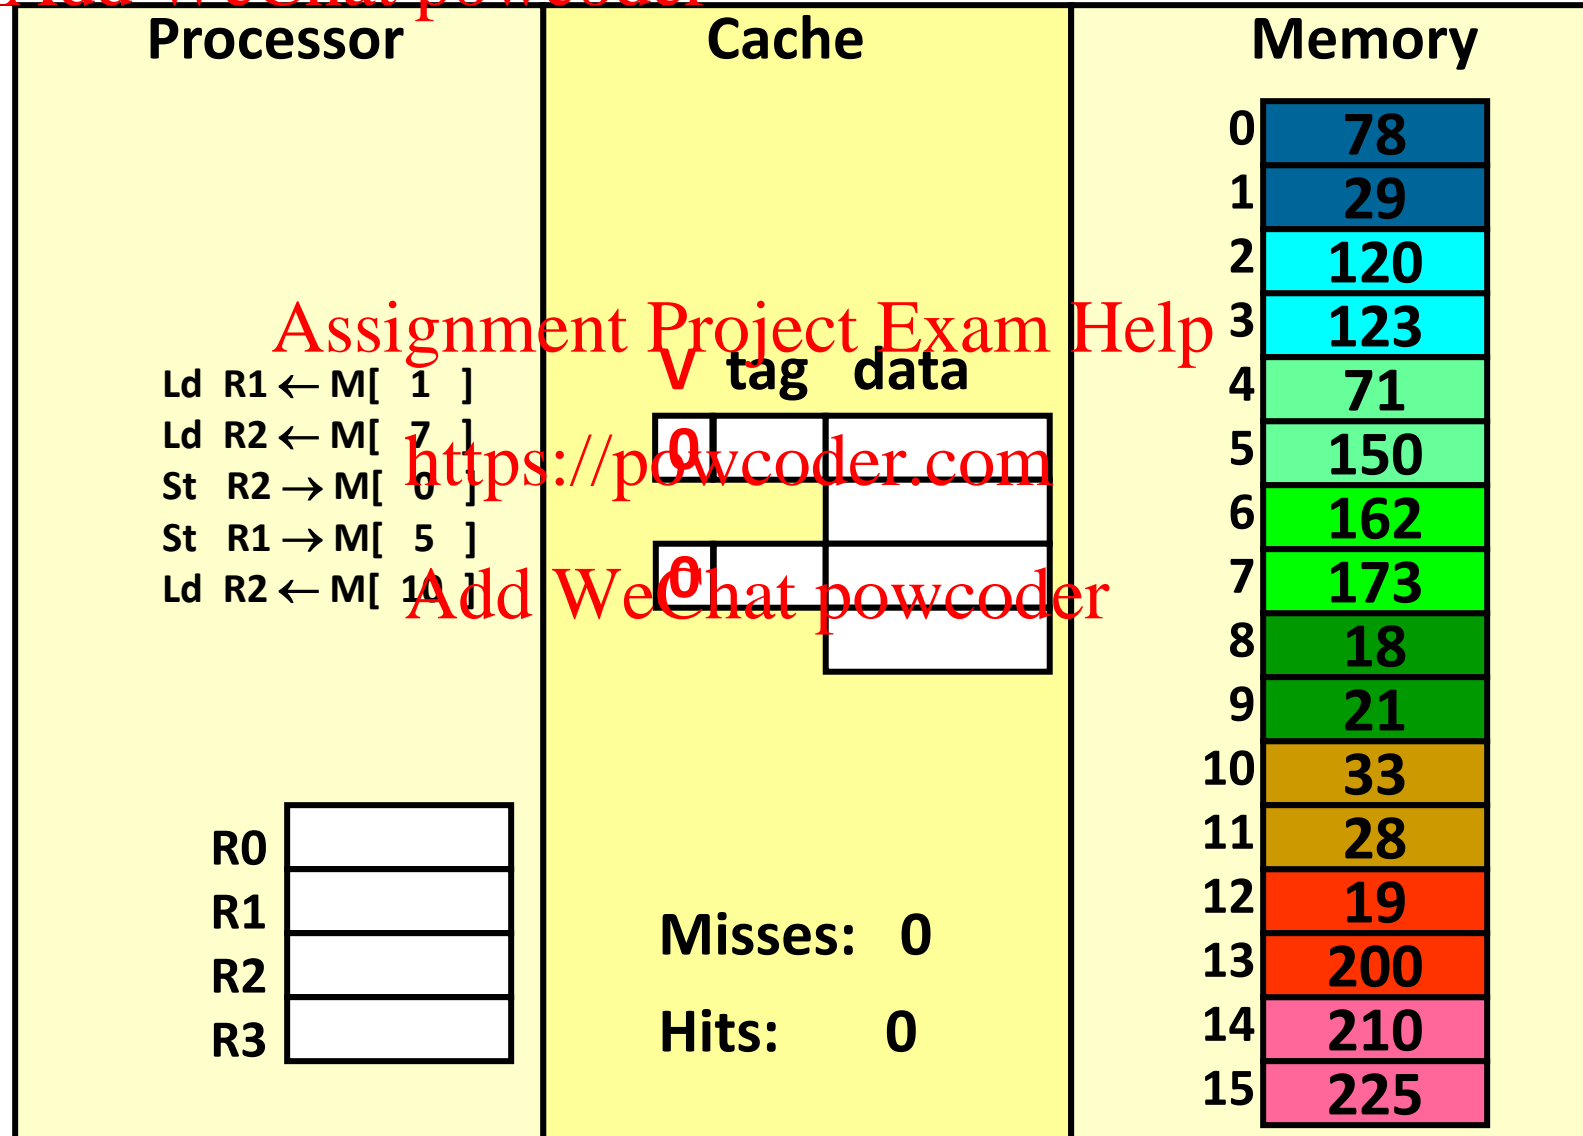

yes - allocate-on-write policy

no - directly write to memory, no allocate-on-write policy

How many reads/writes to main memory in a write-through cache?

Add WeChat powcoder

Each cache miss reads a block (2 bytes in our example) from main memory

Total reads from main memory: 8 bytes

Each store writes a byte to main memory

Assignment Project Exam Help

Total writes to main memory: 2 bytes

<https://powcoder.com>

Add WeChat powcoder

But, cache miss rate $< 20\%$.

total main memory reads due to cache misses \ll main memory writes in a write-through cache

Assignment Project Exam Help

Write-through vs. write-back

Can we also design the cache to **NOT** write all stores to memory immediately?

We can keep the most recent copy in the cache and update the memory **only when** that data is evicted from the cache (a **write-back** policy).

Do we need to write-back all evicted cache blocks?

No, only blocks that have been stored into

Keep a “**dirty bit**”:

- reset when the line is allocated

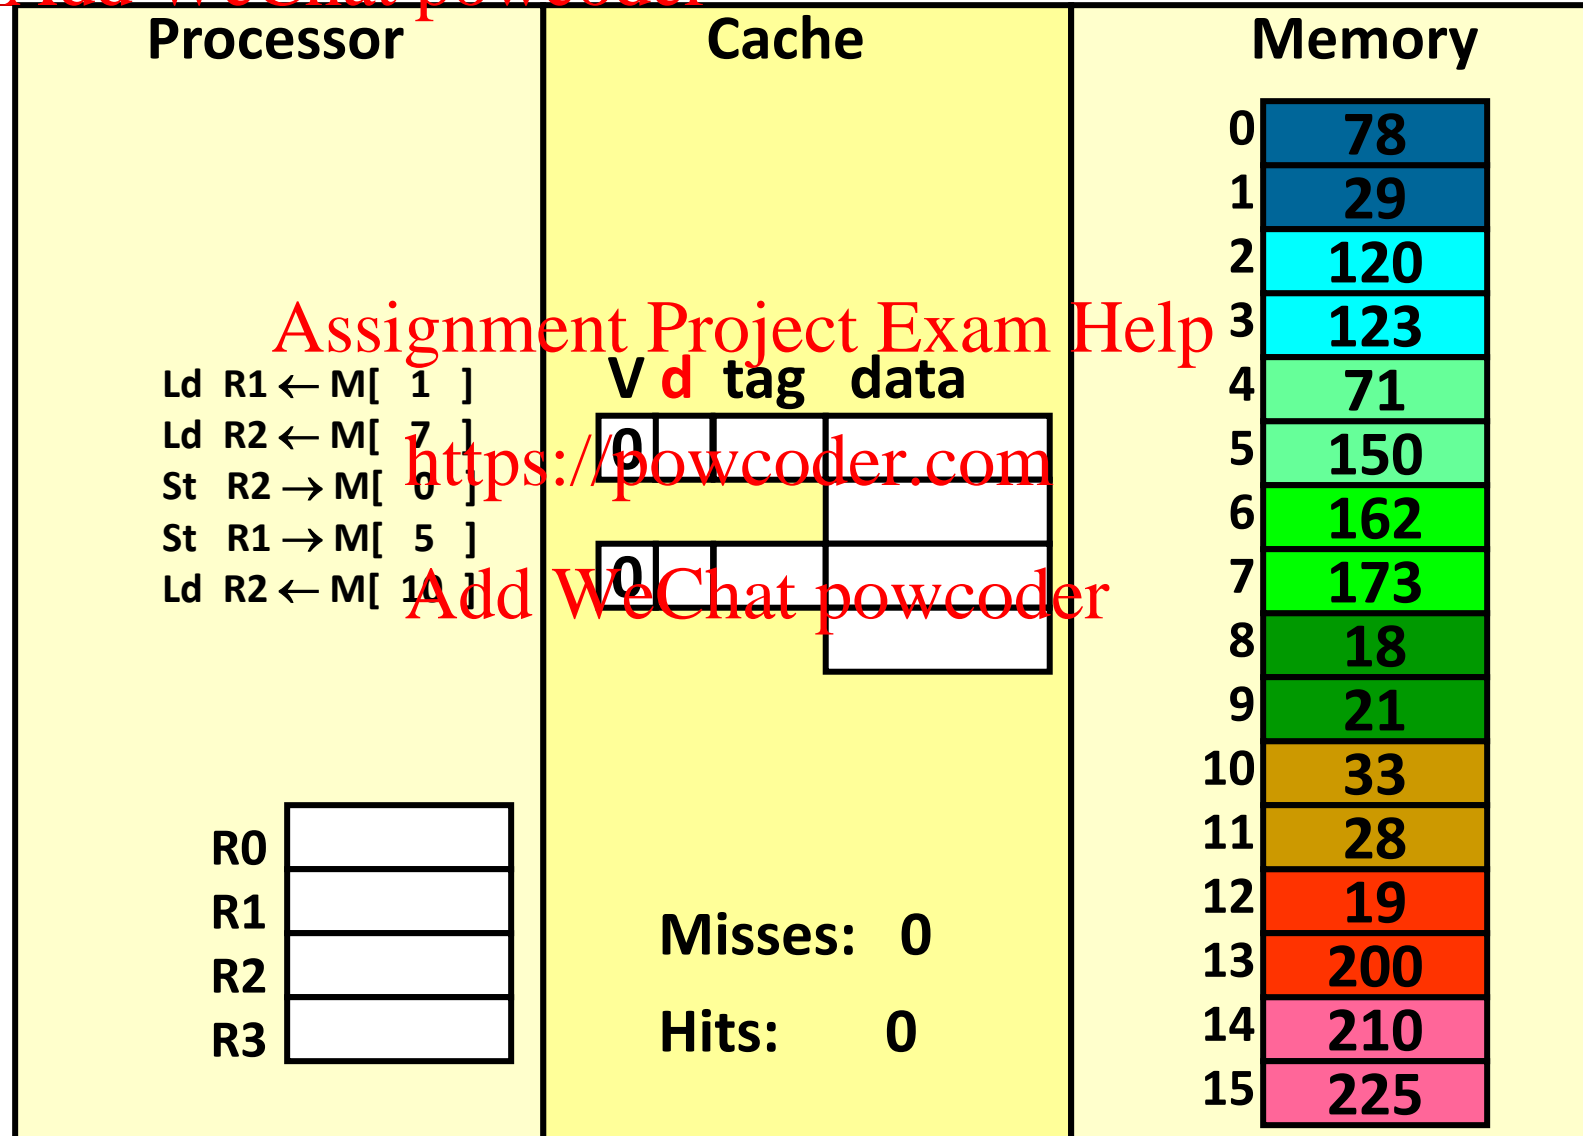

- set when the block is stored into

If a block is “dirty” when evicted, write its data back into memory.
